

THE APIARY · THE WATCHDOG

Doctor

The watchdog that keeps your memory stack alive.

THE PROBLEM

A memory daemon dies at 2am and nothing notices. Next morning your agent has the memory of a goldfish, and you burn twenty minutes re-explaining a codebase it knew yesterday.

THE PROMISE

Doctor stands outside every failure domain it watches. It catches the crash, climbs a repair ladder, and has the daemon back before your next prompt. You never find out it happened.

WHAT YOU GET

Watches everything, every 30s

Probes each daemon and learns the kind of wrong: down, wedged, or degraded in a specific subsystem.

Heals on a ladder

Restart, reinstall after three fails, remove a conflicting package, back off, stop the instant health returns.

Quiet when fine, loud when stuck

A healthy probe is one debug line. When the ladder runs out it writes a structured, do-this-next report.

Safe by construction

Blessed-release updates with automatic rollback. Never reads or deletes your credentials. Full stop.

WHY IT HOLDS UP

✓ Zero dependencies

✓ OS-supervised

✓ No admin needed

✓ macOS · Linux · Windows

SEE IT HOLD UP

Kill honeycomb on purpose. Wait thirty seconds. Run doctor status. It is back, with a fresh last-heal. The failure happened and the fix happened, and you were never on the hook for either.
