The Apiary

FIVE PRODUCTS, ONE MEMORY

LEGION CODE × ACTIVELOOP

What if every AI tool your team uses shared one memory you actually own?

AI assistants are brilliant and forgetful, scattered across tools that never share what they learn. The Apiary is a stack of small, sharp programs that give all of them one shared memory on Deeplake, on infrastructure you control, each solving one stubborn problem. Learn something once, and every agent recalls it everywhere.

What remembers, and where does it live?

Honeycomb is the shared memory, and it lives on Deeplake, reached only by a local daemon, isolated per team and project, with secrets never shown to an agent. What one assistant learns, all of them recall, across tools and machines.

How do agents find the right code and context?

Nectar describes every file by what it does and Deeplake searches by meaning, so agents find the right code and notes even when nobody used the right words. Recall gets sharper as your team uses it, not noisier.

What keeps it running, and how do we see it?

Doctor watches the stack and heals what breaks before the next prompt, and Hive serves the whole dashboard at one local address. You get a system that repairs itself and a single honest status view.

Does it scale past one machine, safely?

Yes. Queen coordinates identity, presence, and org-wide ROI across a fleet without ever reading your memory content. It is one memory, one hive, on Deeplake, and it stays yours. (Queen coming soon.)
