

Doctor

THE WATCHDOG

THE APIARY · LEGION CODE × ACTIVELOOP

What does a silent memory outage cost you across a whole team?

Your engineers' memory runs on local daemons, and a daemon that dies quietly costs every developer it touches: forgotten sessions and time re-explaining code the agent already knew. Doctor is the watchdog that stands outside every failure it watches, heals the stack automatically, and keeps it current safely, so the outage and the fix both happen without a ticket.

Who fixes the stack when it breaks?

Doctor does, on its own. It probes every daemon every 30 seconds, diagnoses the kind of failure, and repairs it on a backoff ladder, escalating with a structured report only when it genuinely cannot. Your team stays in flow instead of filing tickets.

How do we roll out updates without breaking machines?

Doctor auto-updates only behind a blessed-release gate: a version must be explicitly approved, the update is verified healthy, and a failed verify rolls back on its own. One bad release cannot spread across your fleet.

Is it a security liability?

No. Doctor is zero-dependency, runs per-user with no admin rights, and has no code that can read or delete credentials. Its escalation reports land on a local status page first and never carry your code or secrets.

How much operational overhead does it add?

Almost none. It is deliberately boring: silent when healthy, supervised by the OS so it survives reboots, and harder to kill than what it watches. The whole point is that nobody has to think about it.
