

THE APIARY · THE UNDERSTANDING LAYER

Nectar

Find code by meaning, not by file name.

THE PROBLEM

Ask your agent where you handle logins and it hunts for login.ts. But the login logic lives in session-refresh.ts, three folders deep, and no name search will ever guess it. Dead end, every time.

THE PROMISE

Nectar gives every file a short plain-language description of what it actually does, so your agent matches on meaning instead of names. You ask the same questions and get the right files back.

WHAT YOU GET

Meaning, not matching

Nectar reads each file and writes down what it does, like refreshes login tokens on each authenticated request.

Quietly current

Descriptions are written once and kept up to date as files change, moved, or renamed. You do nothing differently.

Fewer dead ends

Your agent points at the file that does the work, not the file that happens to share a name with your question.

Team-ready

Once one person builds the understanding, the rest of the team gets it for free when they pull the project.

WHY IT HOLDS UP

✓ Meaning-based recall

✓ Portable registry

✓ Team-ready

✓ Surfaces via Honeycomb

SEE IT HOLD UP

Ask a meaning-shaped question, where do we handle user authentication, and the right files come back regardless of what they are called. It is the index at the back of a book, but one that actually read every chapter.

Get started

One command. The whole stack, Doctor included.

`curl -fsSL https://get.theapiary.sh | sh`
